9.2 – Disadvantages

1. Dependency On Data Quality: The correctness of the analysis strongly depends on the accuracy and completeness of the collected information since inaccurate or incomplete data may affect the analysis.

2. Narrow Scope of Research: The project will only examine issues related to electricity consumption and not cover topics such as electricity generation or pricing.

3. Using Historical Data Only: Using historical data, one cannot obtain up-to-date insights into electricity consumption processes.

4. Influence of External Factors Is Not Considered: Weather, demographic, economic, and other external factors may influence electricity consumption; however, they are not always taken into account.

5. Necessary User's Skills: To analyze data using Tableau efficiently, users must have certain knowledge about Tableau software and data analysis tools.

6. Predictions Uncertainty: The future needs of electricity consumers may not coincide with predictions made by analysts due to possible changes in electricity consumption patterns.

7. Inconsistent Datasets: Inconsistent data or lack of it may affect the outcomes of the analysis significantly.

8. Reduced Dashboards' Performance: A large number of elements or complicated visualizations can reduce dashboards' performance.

9. Possible Misinterpretation of Charts: A large number of elements or complicated visualizations can reduce dashboards' performance.

10. Regular Updates Needed: A large number of elements or complicated visualizations can reduce dashboards' performance.
